Abstract

Optokinetic nystagmus is rhythmic eye movements, back and forth, with a slow and fast phase, when the eyes are presented for full-field visual stimulus. OKN was recorded in 10 healthy subjects and 10 patients suffering from vertigo, for four conditions: stripes moving 30 o/s left and right and 60 o/s left and right.

The aim of the present study was to analyze if the optokinetic stimulation intensity, stripes moving with angular velocity of 30 and 60 o/s, below and above the normal threshold for smooth pursuit function, influences the scaling properties of the integrated optokinetic nystagmus inter-saccadic intervals in a group of patients suffering from vertigo and a group of healthy subjects.

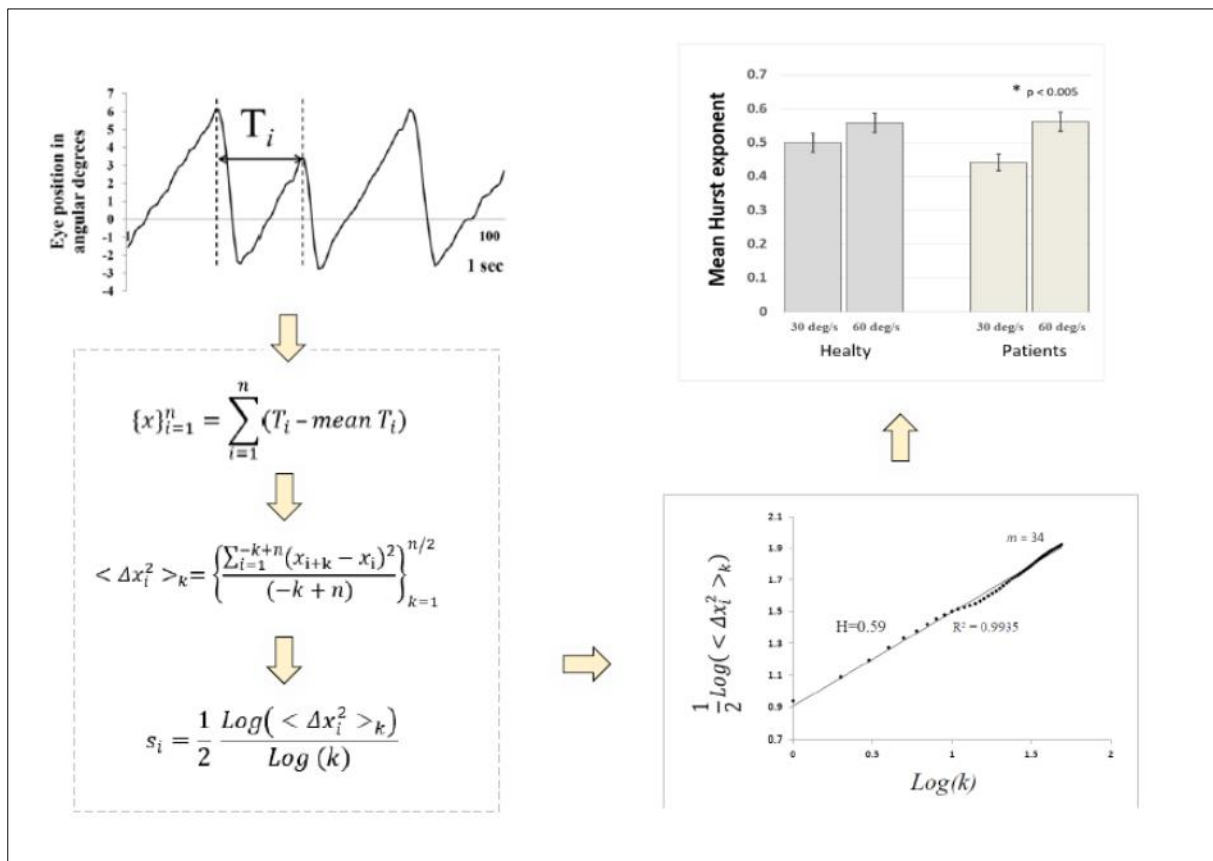

Calculating the scaling, the spread over time, for the integrated optokinetic nystagmus inter-saccadic intervals, the time intervals between the onsets of consecutive fast components, shows lower Hurst exponent for velocity stimulation of 30o/s compared to 60o/s for both patients and health subjects, but only reach statistical significance for the group of patients. This result is a novel finding.

Graphical Abstract

1 Introduction

In an earlier study it was shown that the pattern of the optokinetic nystagmus (OKN) amplitude sequence scales statistically different compared to random permutations of the same numbers [1]. The aim of the present study was to analyze if the optokinetic stimulation intensity, stripes moving with angular velocity of 30 and 60 °/s, below and above the normal threshold for smooth pursuit function, influences the scaling properties of the integrated optokinetic nystagmus inter-saccadic intervals in a group of patients suffering from vertigo and a group of healthy subjects. The literature has not yet reported any changes in the dynamic patterns of nystagmus intersaccadic-interval sequence between optokinetic stimulation below and above the normal threshold for smooth pursuit function. It would therefore be of interest, and a novel finding, to find a parameter that can detect such a difference.

1.1 Optokinetic nystagmus

When presented with a moving image, the eyes respond with a movement in the same direction as the image, interrupted by quick/fast resetting phases [1-5]. Optokinetic nystagmus inter-saccadic interval (OKN-ISI) is the time intervals between the onsets of consecutive fast components.

1.2 Hurst exponent

The scaling coefficient H , the Hurst exponent, is a measure of memory of a time series with the three properties [6-11]. $H < 0.5$ corresponds to a process with negative autocorrelation. $H = 0.5$ corresponds to a time-integrated white noise time series with no memory. $H > 0.5$ corresponds to a process with positive autocorrelation.

2 Material and methods

2.1 Subject

Ten patients suffering from vertigo and ten healthy subjects were included in the study. The patients included were consecutive patients examined at the Vestibular and Balance laboratory at the Department of Otorhinolaryngology and Head and Neck Surgery at Haukeland University Hospital, Norway. The healthy subjects were recruited among healthy hospital staff. All methods were carried out in accordance with and approved by the Regional Committee for Medical and Health Research Ethics (REK 2012-1075). Informed consent was obtained from all subjects.

2.2 Recording technique

Horizontal eye movements were recorded with two electrodes (Ag-AgCl skin electrodes), which were placed laterally to each eye, along with a reference electrode at the center of the forehead. The signal was amplified (10 s time constant and an upper cut-off frequency of 30 Hz) and digitized into a computer, using 12 bit A/D resolution and 100 Hz sampling frequency (sampling time $\tau_s = 0.01$).

OKN was recorded for four conditions: stripes moving 30 °/s left and right and 60 °/s left and right. This gives a total of 40 recordings: 20 for 30 °/s -, and 20 for 60 °/s velocity.

2.3 Optokinetic stimulation and registration

OKN was obtained by stimulating the visual field with 3.75° width vertical light stripes separated by 11.25° width dark stripes. A slit projector presented the stripes on the inside of a hemispherical screen (100 cm in diameter). The subjects were sitting in front of a screen in a darkened room with the head restrained. The subjects were instructed to not follow the stripes with the eyes but to focus their vision on the screen, allowing the optokinetic reflex to control the eye movements. Recordings were performed with the movement of the stripes at a velocity of 30°/s and at 60°/s, which are below and above the normal threshold for smooth pursuit function [12, 13]. Each recording lasted for 1 min. Figure 1 shows a 1 s recording of OKN.

Figure 1 A 1 s registration of an optokinetic time series. Upward direction represents eye movement to the right and downward direction represents eye movement to the left

2.4 Methods and analysis

Analyzing methods for distinguishing random behavior from long-term correlation/memory in time series have been described [14]. It has been shown that the mean square displacement exhibit scaling laws proportional to Δt^{2H} [15].

$$\langle \Delta x^2 \rangle = \langle (x_i - x_{i-\Delta t})^2 \rangle \sim \Delta t^{2H} \quad \text{————— (1)}$$

$\langle \Delta x^2 \rangle$ is the mean square displacement, Δt is the time interval and H is the Hurst exponent. If data are independent, i.e. no memory, the displacement will increase with the square root of time and $H = 1/2$.

2.4.1 The algorithm

The algorithm was applied to the integrated - the cumulative sum - of the nystagmus intersaccadic-interval sequence series, T_i , adjusted for the mean.

$$\{x\}_{i=1}^n = \sum_{i=1}^n (T_i - \text{mean } T_i) \text{-----} (2)$$

Where;

$$\text{mean } T_i = \sum_{i=1}^n \frac{T_i}{n} \text{-----} (3)$$

The time series, x_i , represents the integrated OKN-ISI sequence. A 1 min recording gives approximately $n = 160$ nystagmus beats.

First, we calculated the mean square displacement $\langle \Delta x^2 \rangle$ in measure of number of nystagmus inter-saccadic intervals k_i .

$$\langle \Delta x_i^2 \rangle_k = \left\{ \frac{\sum_{i=1}^{-k+n} (x_{i+k} - x_i)^2}{(-k + n)} \right\}_{k=1}^{n/2} \text{-----} (4)$$

Then, from the scaling properties, we find the slope s_i .

$$s_i = \frac{1}{2} \frac{\text{Log}(\langle \Delta x_i^2 \rangle_k)}{\text{Log}(k)} \text{-----} (5)$$

The scaling was then calculated using the method of least square to fit straight lines for 1 to m ($m = 4$ to $n/2$) nystagmus inter-saccadic intervals (see Fig. 2).

Figure 2 Plots of $\text{Log}(k)$ versus $\frac{1}{2} \text{Log}(\langle \Delta x_i^2 \rangle_k)$ for a sequence of integrated optokinetic nystagmus inter-saccadic interval for scaling length $m = 36$

Since the results of the Shapiro-Wilk test showed that the data was normally distributed ($P_{V30} = 0.949$ and $P_{V60} = 0.512$), paired Student t-test was used to compare the mean values of the Hurst exponent parameters for velocity stimulation of $30^\circ/\text{s}$ and $60^\circ/\text{s}$ for the group of healthy subjects and for the group of vertigo patients.

3 Results

Comparing the Hurst exponent for velocity stimulation of 30°/s and 60°/s for the group of patients for various scaling length shows highest significant differences for scaling of $m = 36$ nystagmus inter-saccadic intervals ($p = 0.00319$) (see Fig. 3). No significance was found for the group of healthy subjects.

Figure 3 Plots of the significant level p for the difference between velocity stimulation of 30°/s and 60°/s for the group of patients for various scaling length m . Highest significant differences is found for scaling length of $m = 36$

Figure 4 Mean and standard error of the Hurst exponent for OKN stimulation of 30°/s and 60°/s velocity for scaling length $m = 36$ for the groups of healthy subjects and vertigo patients. * $p < 0.005$ ($n = 20$)

Figure 4 shows the mean and standard error of the scaling for velocity stimulation of 30°/s and 60°/s for scaling length $m = 36$ for patients and healthy subjects. The mean Hurst exponent is lower for stimulation of 30°/s compared to 60°/s for both the patients and health subjects, but it only reaches statistical significance ($p < 0.005$) for the group of patients. The values for mean, standard deviation and standard error are summarized in Table 1.

Table 1 Mean, standard deviation, and standard error of the Hurst exponent

	30o/s			60o/s		
	Mean	SD	SE	Mean	SD	SE
Healthy subjects	0.4996	0.1226	0,0274	0.5589	0.1284	0,0287
Patients	0.4416	0.1076	0,0241	0.5622	0.1275	0,0285

The mean, standard deviation, and standard error of the Hurst exponent for OKN stimulation of 30o/s and 60 o/s velocity for scaling length $m = 36$ for the groups of healthy subjects and vertigo patients ($n = 20$).

4 Discussion

The mechanism behind the regulation of the various nystagmus component, related to the dynamical behavior when responding to the environment, is still unexplored. In an earlier study surrogate data analysis shows that the pattern of the OKN amplitude sequence is statistically different compared to the random permutations of the same numbers [1]. The present study shows that there is difference in the scaling, the spread of the integrated optokinetic nystagmus inter-saccadic interval over time, when increasing the optokinetic stimulation from 30 to 60 °/s, implicating that the system switch to a different dynamical behavior

5 Conclusion

The result of discriminating finding between healthy and patients, based on statistical differences of the scaling between optokinetic stimulations of 30°/s and 60°/s velocity is a novel finding. This finding is a supplement for better understanding of the mechanism behind the regulation of the nystagmus sequence when reacting to the environment and can be helpful in diagnose vertigo patients.

Compliance with ethical standards

Statement of ethical approval

All methods were carried out in accordance with and approved by the Regional Committee for Medical and Health Research Ethics (REK 2012-1075).

Statement of informed consent

Ten patients suffering from vertigo and ten healthy subjects were included in the study. The patients included were consecutive patients examined at the Vestibular and Balance laboratory at the Department of Otorhinolaryngology and Head and Neck Surgery at Haukeland University Hospital, Norway. The healthy subjects were recruited among healthy hospital staff. Informed consent was obtained from all individual participants included in the study.
